

Self Destructing Secret Agency Message Service

Imagine receiving the task to create a service that can be used to store secret messages that'll self destruct after fetching them.

Following requirements must be met:

1. Environment

- Crypto service and NATS server run in Docker containers, set up via compose file
- Crypto service is a spring boot application

2. Business Logic

- The password cannot be set by the secret message creator, must be safely auto generated
- The password cannot be saved in the crypto service
- The recipient will receive password and id via a second secure factor. May it be by a secret mail box on a train station or via pidgeon.
- The recipient has three tries to enter the right password. If the recipient fails, the message will be deleted.
- As soon as the recipient successfully received the message, delete the message.

General notes:

- You will probably need at least eight hours, do not invest more than 16 hours
- Deliver a Gradle or Maven project as a ZIP file
- Add a README.md containing instructions for running the project
- Most important is a runnable project
- NATS communication must work
- If some other features are not (completely) implemented, that's OK, but at least create method stubs with logging, what would be done
- Please follow the [Google Java Style Guide](#)

Bonus points for:

- Proper error handling
- Using Graal VM for the Crypto Service Container to keep the footprint small
- Having a scheduler that'll automatically delete all messages older than two days
- Being able to configure max tries, scheduler auto deletion date and password length via environment parameter
- Using nkey and TLS for the connection between jUnit NATS client and NATS, as well as NATS and the Crypto Service
